

The EP matrix site (D-14) inverts $\nu \text{Herm}(J)$ and therefore needs J PSD. It is, on D1. It is not, on D2.

Whisker = $[\lambda_{\min}, \lambda_{\max}]$, bar = 25th percentile..median of the 48×64 eigenvalues at that σ . y is symlog (linear below 10^{-3}): the sign change and the near-zero bulk are both on the page, nothing is clipped.

On D2 at $N=1\text{e}4$ the same n_{neg} counts are 8.0 / 10.6 / 11.2 / 7.8 (logs/jacspecc_D2_N10000.log) -- the same picture at 1/16 of the data. The fitted GMM on D2 stays POSITIVE but reaches 8×10^{-5} (numbers beside its lower whisker): it is near the PSD boundary, not on it.
