

16x the data and a later epoch move nothing on D2;
the same code and budget on D1 is valid everywhere

D1 and D2 have their own frozen sigma grids (0.0329-0.791 and 0.0331-0.845); each curve is drawn against its OWN grid.

D1's $f(\lambda_{\min} < 0)$ is 0.000 at all 20 points, but its $asym(J_r)$ is NOT zero -- it rises from $1.9e-3$ to $9.8e-2$.

The learned D1 Jacobian is PSD everywhere and only approximately symmetric, which is why both panels are drawn.
